- Modeling
- Constraints
- E-R Diagram
- Design Issues
- Weak Entity Sets
- Extended E-R Features
- Design of the Bank Database
- Reduction to Relation Schemas
- Database Design
- UML
A *database* can be modeled as:
- a collection of entities,
- relationship among entities.

An **entity** is an object that exists and is distinguishable from other objects.
- Example: specific person, company, event, plant

Entities have **attributes**
- Example: people have *names* and *addresses*

An **entity set** is a set of entities of the same type that share the same properties.
- Example: set of all persons, companies, trees, holidays
### Entity Sets *instructor* and *student*

#### Instructor

<table>
<thead>
<tr>
<th>instructor_ID</th>
<th>instructor_name</th>
</tr>
</thead>
<tbody>
<tr>
<td>76766</td>
<td>Crick</td>
</tr>
<tr>
<td>45565</td>
<td>Katz</td>
</tr>
<tr>
<td>10101</td>
<td>Srinivasan</td>
</tr>
<tr>
<td>98345</td>
<td>Kim</td>
</tr>
<tr>
<td>76543</td>
<td>Singh</td>
</tr>
<tr>
<td>22222</td>
<td>Einstein</td>
</tr>
</tbody>
</table>

#### Student

<table>
<thead>
<tr>
<th>student-ID</th>
<th>student_name</th>
</tr>
</thead>
<tbody>
<tr>
<td>98988</td>
<td>Tanaka</td>
</tr>
<tr>
<td>12345</td>
<td>Shankar</td>
</tr>
<tr>
<td>00128</td>
<td>Zhang</td>
</tr>
<tr>
<td>76543</td>
<td>Brown</td>
</tr>
<tr>
<td>76653</td>
<td>Aoi</td>
</tr>
<tr>
<td>23121</td>
<td>Chavez</td>
</tr>
<tr>
<td>44553</td>
<td>Peltier</td>
</tr>
</tbody>
</table>
Relationship Sets

- A **relationship** is an association among several entities.
  Example:
  
  - $44553$ (Peltier) **advisor** $22222$ (Einstein)
  - student entity relationship set instructor entity

- A **relationship set** is a mathematical relation among $n \geq 2$ entities, each taken from entity sets

  \[ \{(e_1, e_2, \ldots, e_n) \mid e_1 \in E_1, e_2 \in E_2, \ldots, e_n \in E_n\} \]

  where $(e_1, e_2, \ldots, e_n)$ is a relationship

  - Example:
    
    $(44553,22222) \in \text{advisor}$
Relationship Set \textit{advisor}

\begin{itemize}
  \item \textbf{instructor}
    \begin{itemize}
      \item 76766  Crick
      \item 45565  Katz
      \item 10101  Srinivasan
      \item 98345  Kim
      \item 76543  Singh
      \item 22222  Einstein
    \end{itemize}
  \item \textbf{student}
    \begin{itemize}
      \item 98988  Tanaka
      \item 12345  Shankar
      \item 00128  Zhang
      \item 76543  Brown
      \item 76653  Aoi
      \item 23121  Chavez
      \item 44553  Peltier
    \end{itemize}
\end{itemize}
An **attribute** can also be property of a relationship set.

For instance, the *advisor* relationship set between entity sets *instructor* and *student* may have the attribute *date* which tracks when the student started being associated with the advisor.
Degree of a Relationship Set

- **binary relationship**
  - involve two entity sets (or degree two).
  - most relationship sets in a database system are binary.

- Relationships between more than two entity sets are rare. Most relationships are binary. (More on this later.)
  - Example: *students* work on research *projects* under the guidance of an *instructor*.
  - relationship *proj_guide* is a ternary relationship between *instructor, student*, and *project*
Attributes

- An entity is represented by a set of attributes, that is descriptive properties possessed by all members of an entity set.
  - Example:
    - instructor = (ID, name, street, city, salary)
    - course = (course_id, title, credits)

- Domain – the set of permitted values for each attribute

- Attribute types:
  - Simple and composite attributes.
  - Single-valued and multivalued attributes
    - Example: multivalued attribute: phone_numbers
  - Derived attributes
    - Can be computed from other attributes
    - Example: age, given date_of_birth
Composite Attributes

- Composite attributes: name
  - First_name
  - Middle_initial
  - Last_name

- Component attributes: address
  - Street
  - City
  - State
  - Postal_code
  - Street_number
  - Street_name
  - Apartment_number
Mapping Cardinality Constraints

- Express the number of entities to which another entity can be associated via a relationship set.
- Most useful in describing binary relationship sets.
- For a binary relationship set the mapping cardinality must be one of the following types:
  - One to one
  - One to many
  - Many to one
  - Many to many
Mapping Cardinalities

One to one

One to many

Note: Some elements in $A$ and $B$ may not be mapped to any elements in the other set
Mapping Cardinalities

Many to one

Note: Some elements in A and B may not be mapped to any elements in the other set

Many to many
Keys

- A **super key** of an entity set is a set of one or more attributes whose values uniquely determine each entity.

- A **candidate key** of an entity set is a minimal super key
  - *ID* is candidate key of *instructor*
  - *course_id* is candidate key of *course*

- Although several candidate keys may exist, one of the candidate keys is selected to be the **primary key**.
Keys for Relationship Sets

The combination of primary keys of the participating entity sets forms a super key of a relationship set.

- \((s\_id, i\_id)\) is the super key of advisor

- **NOTE:** this means *a pair of entity sets can have at most one relationship in a particular relationship set.*
  - Example: if we wish to track multiple meeting dates between a student and her advisor, we cannot assume a relationship for each meeting. We can use a multivalued attribute though

- Must consider the mapping cardinality of the relationship set when deciding what are the candidate keys

- Need to consider semantics of relationship set in selecting the *primary key* in case of more than one candidate key
Suppose we have entity sets

- *instructor*, with attributes including *dept_name*
- *department*

and a relationship

- *inst_dept* relating *instructor* and *department*

Attribute *dept_name* in entity *instructor* is redundant since there is an explicit relationship *inst_dept* which relates instructors to departments

- The attribute replicates information present in the relationship, and should be removed from *instructor*
- BUT: when converting back to tables, in some cases the attribute gets reintroduced, as we will see.
Rectangles represent entity sets.

Diamonds represent relationship sets.

Attributes listed inside entity rectangle

Underline indicates primary key attributes
Entity With Composite, Multivalued, and Derived Attributes

```
instructor

ID
name
  first_name
  middle_initial
  last_name
address
  street
    street_number
    street_name
    apt_number
  city
  state
  zip
{ phone_number }
date_of_birth
age ( )
```
Relationship Sets with Attributes

- **instructor**
  - ID
  - name
  - salary

- **student**
  - ID
  - name
  - tot_cred

- **date**

- **advisor**
Entity sets of a relationship need not be distinct

- Each occurrence of an entity set plays a “role” in the relationship

- The labels “course_id” and “prereq_id” are called roles.
Cardinality Constraints

- We express cardinality constraints by drawing either a directed line (→), signifying “one,” or an undirected line (—), signifying “many,” between the relationship set and the entity set.

- One-to-one relationship:
  - A student is associated with at most one instructor via the relationship advisor
  - A student is associated with at most one department via stud_dept
One-to-One Relationship

- one-to-one relationship between an instructor and a student
  - an instructor is associated with at most one student via advisor
  - and a student is associated with at most one instructor via advisor
One-to-Many Relationship

- one-to-many relationship between an instructor and a student
  - an instructor is associated with several (including 0) students via advisor
  - a student is associated with at most one instructor via advisor,
Many-to-One Relationships

- In a many-to-one relationship between an instructor and a student,
  - an instructor is associated with at most one student via advisor,
  - and a student is associated with several (including 0) instructors via advisor
Many-to-Many Relationship

- An instructor is associated with several (possibly 0) students via *advisor*
- A student is associated with several (possibly 0) instructors via *advisor*
Participation of an Entity Set in a Relationship Set

- Total participation (indicated by double line): every entity in the entity set participates in at least one relationship in the relationship set
  - E.g., participation of section in sec_course is total
    - every section must have an associated course
- Partial participation: some entities may not participate in any relationship in the relationship set
  - Example: participation of instructor in advisor is partial
Cardinality limits can also express participation constraints.
E-R Diagram with a Ternary Relationship

- **instructor**
  - ID
  - name
  - salary

- **project**
  - ...

- **student**
  - ID
  - name
  - tot_cred

**proj_guide**
Cardinality Constraints on Ternary Relationship

- We allow at most one arrow out of a ternary (or greater degree) relationship to indicate a cardinality constraint.
- E.g., an arrow from *proj_guide* to *instructor* indicates each student has at most one guide for a project.
- If there is more than one arrow, there are two ways of defining the meaning.
  - E.g., a ternary relationship $R$ between $A$, $B$ and $C$ with arrows to $B$ and $C$ could mean
    1. each $A$ entity is associated with a unique entity from $B$ and $C$ or
    2. each pair of entities from $(A, B)$ is associated with a unique $C$ entity, and each pair $(A, C)$ is associated with a unique $B$
  - Each alternative has been used in different formalisms.
  - To avoid confusion we outlaw more than one arrow.
How about doing an ER design interactively on the board? Suggest an application to be modeled.
Weak Entity Sets

- An entity set that does not have a primary key is referred to as a **weak entity set**.
- The existence of a weak entity set depends on the existence of a **identifying entity set**
  - It must relate to the identifying entity set via a total, one-to-many relationship set from the identifying to the weak entity set
  - **Identifying relationship** depicted using a double diamond
- The **discriminator** (or partial key) of a weak entity set is the set of attributes that distinguishes among all the entities of a weak entity set.
- The primary key of a weak entity set is formed by the primary key of the strong entity set on which the weak entity set is existence dependent, plus the weak entity set’s discriminator.
Weak Entity Sets (Cont.)

- We underline the discriminator of a weak entity set with a dashed line.
- We put the identifying relationship of a weak entity in a double diamond.
- Primary key for section – (course_id, sec_id, semester, year)
Weak Entity Sets (Cont.)

- Note: the primary key of the strong entity set is not explicitly stored with the weak entity set, since it is implicit in the identifying relationship.

- If \textit{course\_id} were explicitly stored, \textit{section} could be made a strong entity, but then the relationship between \textit{section} and \textit{course} would be duplicated by an implicit relationship defined by the attribute \textit{course\_id} common to \textit{course} and \textit{section}.
E-R Diagram for a University Enterprise
Reduction to Relational Schemas
Reduction to Relation Schemas

- Entity sets and relationship sets can be expressed uniformly as relation schemas that represent the contents of the database.
- A database which conforms to an E-R diagram can be represented by a collection of schemas.
- For each entity set and relationship set there is a unique schema that is assigned the name of the corresponding entity set or relationship set.
- Each schema has a number of columns (generally corresponding to attributes), which have unique names.
A strong entity set reduces to a schema with the same attributes

\[ \text{student}(ID, \text{name}, \text{tot_cred}) \]

A weak entity set becomes a table that includes a column for the primary key of the identifying strong entity set

\[ \text{section}(\text{course_id}, \text{sec_id}, \text{sem}, \text{year}) \]
A many-to-many relationship set is represented as a schema with attributes for the primary keys of the two participating entity sets, and any descriptive attributes of the relationship set.

Example: schema for relationship set `advisor`

```
advisor = (s_id, i_id)
```
Redundancy of Schemas

- Many-to-one and one-to-many relationship sets that are total on the many-side can be represented by adding an extra attribute to the “many” side, containing the primary key of the “one” side.

- Example: Instead of creating a schema for relationship set $inst\_dept$, add an attribute $dept\_name$ to the schema arising from entity set $instructor$.
For one-to-one relationship sets, either side can be chosen to act as the “many” side
- That is, extra attribute can be added to either of the tables corresponding to the two entity sets

If participation is *partial* on the “many” side, replacing a schema by an extra attribute in the schema corresponding to the “many” side could result in null values

The schema corresponding to a relationship set linking a weak entity set to its identifying strong entity set is redundant.
- Example: The *section* schema already contains the attributes that would appear in the *sec_course* schema
Composite and Multivalued Attributes

- Composite attributes are flattened out by creating a separate attribute for each component attribute.
  - Example: given entity set `instructor` with composite attribute `name` with component attributes `first_name` and `last_name` the schema corresponding to the entity set has two attributes `name_first_name` and `name_last_name`.
    - Prefix omitted if there is no ambiguity.

- Ignoring multivalued attributes, extended instructor schema is:
  - `instructor(ID,
    first_name, middle_initial, last_name,
    street_number, street_name,
    apt_number,
    city,
    state,
    zip,
    { phone_number },
    date_of_birth,
    age ()
  )`
A multivalued attribute $M$ of an entity $E$ is represented by a separate schema $EM$

- Schema $EM$ has attributes corresponding to the primary key of $E$ and an attribute corresponding to multivalued attribute $M$
- Example: Multivalued attribute \textit{phone\_number} of \textit{instructor} is represented by a schema:
  \[ \textit{inst\_phone} = (ID, \textit{phone\_number}) \]
- Each value of the multivalued attribute maps to a separate tuple of the relation on schema $EM$
  - For example, an \textit{instructor} entity with primary key 22222 and phone numbers 456-7890 and 123-4567 maps to two tuples:
    \[(22222, 456-7890) \text{ and } (22222, 123-4567)\]
Special case: entity \textit{time\_slot} has only one attribute other than the primary-key attribute, and that attribute is multivalued

- Optimization: Don’t create the relation corresponding to the entity, just create the one corresponding to the multivalued attribute
- \textit{time\_slot}(time\_slot\_id, day, start\_time, end\_time)
- Caveat: \textit{time\_slot} attribute of \textit{section} (from sec\_time\_slot) cannot be a foreign key due to this optimization
Design Issues

- Use of entity sets vs. attributes

- Use of phone as an entity allows extra information about phone numbers (plus multiple phone numbers)
Design Issues

- **Use of entity sets vs. relationship sets**
  
  Possible guideline is to designate a relationship set to describe an action that occurs between entities.
Design Issues

- **Binary versus n-ary relationship sets**
  Although it is possible to replace any nonbinary \((n\text{-ary, for } n > 2)\) relationship set by a number of distinct binary relationship sets, a \(n\)-ary relationship set shows more clearly that several entities participate in a single relationship.

- **Placement of relationship attributes**
  
  e.g., attribute *date* as attribute of *advisor* or as attribute of *student*
Binary Vs. Non-Binary Relationships

- Some relationships that appear to be non-binary may be better represented using binary relationships
  - E.g., A ternary relationship *parents*, relating a child to his/her father and mother, is best replaced by two binary relationships, *father* and *mother*
    - Using two binary relationships allows partial information (e.g., only mother being known)
  - But there are some relationships that are naturally non-binary
    - Example: *proj_guide*
In general, any non-binary relationship can be represented using binary relationships by creating an artificial entity set.

- Replace \( R \) between entity sets \( A, B \) and \( C \) by an entity set \( E \), and three relationship sets:
  1. \( R_A \), relating \( E \) and \( A \)
  2. \( R_B \), relating \( E \) and \( B \)
  3. \( R_C \), relating \( E \) and \( C \)
- Create a special identifying attribute for \( E \)
- Add any attributes of \( R \) to \( E \)
- For each relationship \((a_i, b_i, c_i)\) in \( R \), create
  1. a new entity \( e_i \) in the entity set \( E \)
  2. add \((e_i, a_i)\) to \( R_A \)
  3. add \((e_i, b_i)\) to \( R_B \)
  4. add \((e_i, c_i)\) to \( R_C \)
Converting Non-Binary Relationships (Cont.)

- Also need to translate constraints
  - Translating all constraints may not be possible
  - There may be instances in the translated schema that cannot correspond to any instance of $R$
    - Exercise: *add constraints to the relationships $R_A$, $R_B$ and $R_C$ to ensure that a newly created entity corresponds to exactly one entity in each of entity sets $A$, $B$ and $C*
  - We can avoid creating an identifying attribute by making $E$ a weak entity set (described shortly) identified by the three relationship sets
Extended ER Features
Extended E-R Features: Specialization

- Top-down design process; we designate subgroupings within an entity set that are distinctive from other entities in the set.
- These subgroupings become lower-level entity sets that have attributes or participate in relationships that do not apply to the higher-level entity set.
- Depicted by a triangle component labeled ISA (E.g., instructor “is a” person).
- **Attribute inheritance** – a lower-level entity set inherits all the attributes and relationship participation of the higher-level entity set to which it is linked.
Specialization Example

- **person**
  - ID
  - name
  - address

- **employee**
  - salary

- **student**
  - tot_credits

- **instructor**
  - rank

- **secretary**
  - hours_per_week
Extended ER Features: Generalization

- **A bottom-up design process** – combine a number of entity sets that share the same features into a higher-level entity set.

- Specialization and generalization are simple inversions of each other; they are represented in an E-R diagram in the same way.

- The terms specialization and generalization are used interchangeably.
Specialization and Generalization (Cont.)

- Can have multiple specializations of an entity set based on different features.
  
- E.g., `permanent_employee` vs. `temporary_employee`, in addition to `instructor` vs. `secretary`

- Each particular employee would be
  
  - a member of one of `permanent_employee` or `temporary_employee`,
  
  - and also a member of one of `instructor`, `secretary`

- The ISA relationship also referred to as **superclass - subclass** relationship
Design Constraints on a Specialization/Generalization

- Constraint on which entities can be members of a given lower-level entity set.
  - condition-defined
    - Example: all customers over 65 years are members of senior-citizen entity set; senior-citizen ISA person.
  - user-defined

- Constraint on whether or not entities may belong to more than one lower-level entity set within a single generalization.
  - **Disjoint**
    - an entity can belong to only one lower-level entity set
    - Noted in E-R diagram by having multiple lower-level entity sets link to the same triangle
  - **Overlapping**
    - an entity can belong to more than one lower-level entity set
Completeness constraint -- specifies whether or not an entity in the higher-level entity set must belong to at least one of the lower-level entity sets within a generalization.

- **total**: an entity must belong to one of the lower-level entity sets
- **partial**: an entity need not belong to one of the lower-level entity sets
Consider the ternary relationship *proj_guide*, which we saw earlier.

Suppose we want to record evaluations of a student by a guide on a project.
Aggregation (Cont.)

- Relationship sets `eval_for` and `proj_guide` represent overlapping information
  - Every `eval_for` relationship corresponds to a `proj_guide` relationship
  - However, some `proj_guide` relationships may not correspond to any `eval_for` relationships
    - So we can’t discard the `proj_guide` relationship
- Eliminate this redundancy via aggregation
  - Treat relationship as an abstract entity
  - Allows relationships between relationships
  - Abstraction of relationship into new entity
Aggregation (Cont.)

- Without introducing redundancy, the following diagram represents:
  - A student is guided by a particular instructor on a particular project
  - A student, instructor, project combination may have an associated evaluation
Representing Specialization via Schemas

- Method 1:
  - Form a schema for the higher-level entity
  - Form a schema for each lower-level entity set, include primary key of higher-level entity set and local attributes

<table>
<thead>
<tr>
<th>schema</th>
<th>attributes</th>
</tr>
</thead>
<tbody>
<tr>
<td>person</td>
<td>ID, name, street, city</td>
</tr>
<tr>
<td>student</td>
<td>ID, tot_cred</td>
</tr>
<tr>
<td>employee</td>
<td>ID, salary</td>
</tr>
</tbody>
</table>

- Drawback: getting information about an employee requires accessing two relations, the one corresponding to the low-level schema and the one corresponding to the high-level schema
Method 2:

- Form a schema for each entity set with all local and inherited attributes
  
<table>
<thead>
<tr>
<th>schema</th>
<th>attributes</th>
</tr>
</thead>
<tbody>
<tr>
<td>person</td>
<td>ID, name, street, city</td>
</tr>
<tr>
<td>student</td>
<td>ID, name, street, city, tot_cred</td>
</tr>
<tr>
<td>employee</td>
<td>ID, name, street, city, salary</td>
</tr>
</tbody>
</table>

- If specialization is total, the schema for the generalized entity set (person) not required to store information
  
  - Can be defined as a “view” relation containing union of specialization relations
  
  - But explicit schema may still be needed for foreign key constraints

- Drawback: *name*, *street* and *city* may be stored redundantly for people who are both students and employees
To represent aggregation, create a schema containing

- primary key of the aggregated relationship,
- the primary key of the associated entity set
- any descriptive attributes
Schemas Corresponding to Aggregation (Cont.)

- For example, to represent aggregation manages between relationship works_on and entity set manager, create a schema 
  \( \text{eval_for} (s\_ID, \text{project}\_id, i\_ID, \text{evaluation}\_id) \)

- Schema \( \text{proj\_guide} \) is redundant provided we are willing to store null values for attribute \( \text{manager}\_name \) in relation on schema manages
E-R Design Decisions

- The use of an attribute or entity set to represent an object.
- Whether a real-world concept is best expressed by an entity set or a relationship set.
- The use of a ternary relationship versus a pair of binary relationships.
- The use of a strong or weak entity set.
- The use of specialization/generalization – contributes to modularity in the design.
- The use of aggregation – can treat the aggregate entity set as a single unit without concern for the details of its internal structure.
How about doing another ER design interactively on the board?
**Summary of Symbols Used in E-R Notation**

- **E**: entity set
- **R**: relationship set
- **identifying relationship set for weak entity set**
- **total participation of entity set in relationship**

**Attributes**:
- simple (A1)
- composite (A2) and multivalued (A3)
- derived (A4)

- **primary key**
- **discriminating attribute of weak entity set**
Symbols Used in E-R Notation (Cont.)

- **many-to-many relationship**
- **one-to-one relationship**
- **Role name**
- **Role indicator**
- ** ISA: generalization or specialization**
- **Disjoint generalization**
- **Cardinality limits**

Diagram:
- R \rightarrow \text{many-to-one relationship}
- R \leftarrow \text{one-to-one relationship}
- R \rightarrow \text{many-to-many relationship}
- R \rightarrow E \quad 1..n
- E1 \rightarrow E2 \rightarrow E3
- E1 \rightarrow E2 \rightarrow E3
- E1 \rightarrow \text{total (disjoint) generalization}
Alternative ER Notations

  - E1 R E2
UML

- **UML**: Unified Modeling Language
- UML has many components to graphically model different aspects of an entire software system
- UML Class Diagrams correspond to E-R Diagram, but several differences.
ER vs. UML Class Diagrams

**ER Diagram Notation**

- **E**
  - A1
  - M10
  - entity with attributes (simple, composite, multivalued, derived)

- **E1** role1 **R** role2 **E2**
  - binary relationship

- **E1** role1 **R** role2 **E2**
  - relationship attributes

- **E1** **R** 0..* **E2**
  - cardinality constraints

**Equivalent in UML**

- **E**
  - -A1
  - +M10
  - class with simple attributes and methods (attribute prefixes: + = public, -= private, # = protected)

- **E1** role1 **R** role2 **E2**

- **E1** role1 **R** role2 **E2**

- **E1** **R** 0.. * **E2**

*Note reversal of position in cardinality constraint depiction*
ER vs. UML Class Diagrams

**ER Diagram Notation**

*n-ary relationships*

**Equivalent in UML**

*overlapping generalization*

*disjoint generalization*

*Generalization can use merged or separate arrows independent of disjoint/overlapping*
Binary relationship sets are represented in UML by just drawing a line connecting the entity sets. The relationship set name is written adjacent to the line.

The role played by an entity set in a relationship set may also be specified by writing the role name on the line, adjacent to the entity set.

The relationship set name may alternatively be written in a box, along with attributes of the relationship set, and the box is connected, using a dotted line, to the line depicting the relationship set.

Figure 7.14

The diagram shows a relationship between two tables:

- **course** table:
  - course_id
  - title
  - credits

- **section** table:
  - sec_id
  - semester
  - year

The relationship is labeled as `sec_course`, indicating a many-to-many relationship between courses and sections.
**Figure 7.17**

(a) A table labeled `instructor` with columns `ID`, `name`, `salary`, and `phone_number`.

(b) A relationship labeled `inst_phone` between tables `instructor` and `phone`. The `instructor` table has columns `ID`, `name`, and `salary`, while the `phone` table has columns `phone_number` and `location`. 
Figure 7.18

The diagram represents an entity-relationship (ER) model with the following entities and relationships:

- **section_reg**
  - Attributes: sec_id, semester, year

- **registration**
  - Attributes: ...

- **student_reg**

- **section**
  - Attributes: ID, name, tot_cred

This model illustrates the relationships between sections, registrations, and students in a database system context.

**ER Diagram Notation**

- **E**
  - A1
  - M10
  - entity with attributes (simple, composite, multivalued, derived)

- E1 role1 R role2 E2 binary relationship
- E1 role1 R role2 E2 relationship attributes
- E1 |-> 0..* R 0..1 E2 cardinality constraints
- E1 R E2 E3 n-ary relationships
- overlapping generalization
- disjoint generalization

**Equivalent in UML**

- **E**
  - A1
  - M10
  - class with simple attributes and methods (attribute prefixes: + = public, - = private, # = protected)

- E1 role1 R role2 E2
- E1 role1 R role2 E2
- E1 role1 R role2 E2
- E1 role1 R role2 E2
- overlapping
- disjoint
